Assignment 2

Zekai Li S2040608

Question 1

(a) My solution

Rewrite the observations in the form of $X_i^2=Y_i^2I(Y_i\leq C)+C^2I(Y_i>C)=Y_i^2R_i+C^2(1-R_i)$. And contribution of a non censored observation to the likelihood is $P(Y_i>C)=1-F(C)=e^{-\frac{C^2}{2\theta}}$.

Therefore, the likelihood of the observed data is,

$$\begin{split} L(\theta) &= \prod_{i=1}^n \{f(y_i;\theta)^{R_i} [P(Y_i > C)]^{1-R_i} \} \\ &= \frac{\prod_{i=1}^m y_i}{\theta^m} e^{-\sum_{i=1}^m \frac{y_i^2}{2\theta}} e^{-\frac{(n-m)C^2}{2\theta}} \end{split}$$

where $m = \sum_{i=1}^{n} R_i$, so the formula of the log-likelihood equal to 0 is:

$$\begin{split} -\frac{m}{\theta} + \sum_{i=1}^{m} \frac{y_i^2}{2\theta^2} + \frac{(n-m)C^2}{2\theta^2} &= 0 \\ \sum_{i=1}^{n} \frac{R_i^2 y_i^2 + (1-R_i)C^2}{2\theta^2} &= \sum_{i=1}^{n} R_i \\ \sum_{i=1}^{n} \frac{X_i^2}{2\theta^2} &= \sum_{i=1}^{n} R_i \end{split}$$

And we get $\hat{\theta} = \frac{\sum_{i=1}^{n} X_i^2}{2\sum_{i=1}^{n} R_i}$.

(b) My solution

From (a), we know the first gradient of the liklihood is $-\frac{\sum_{i=1}^{n}R_{i}}{\theta}+\sum_{i=1}^{n}\frac{X_{i}^{2}}{2\theta^{2}}$. Therefore, the fisher information would be:

$$\begin{split} \mathcal{I}(\theta) &= -\mathbb{E}\left[\frac{\sum_{i=1}^{n} R_{i}}{\theta^{2}} - \sum_{i=1}^{n} \frac{X_{i}^{2}}{\theta^{3}}\right] \\ &= \sum_{i=1}^{n} \frac{\mathbb{E}[X_{i}^{2}]}{\theta^{3}} - \sum_{i=1}^{n} \frac{\mathbb{E}[R_{i}]}{\theta^{2}} \\ &= \sum_{i=1}^{n} \frac{\left(\int_{0}^{C} y^{2} f(y;\theta) \, dy + C^{2}(1 - F(C))\right)}{\theta^{3}} - \sum_{i=1}^{n} \frac{F(C)}{\theta^{2}} \\ &= \frac{2n}{\theta^{2}} (1 - e^{-\frac{C^{2}}{2\theta}}) - \frac{n}{\theta^{2}} (1 - e^{-\frac{C^{2}}{2\theta}}) \\ &= \frac{n}{\theta^{2}} (1 - e^{-\frac{C^{2}}{2\theta}}) \end{split}$$

(c) My solution

From the asymptotic normality of the maximum likelihood estimator, we know that $\hat{\theta} \sim \mathcal{N}(\theta, \frac{1}{n\mathcal{I}(\theta)}) = \mathcal{N}(\theta, \frac{\theta^2}{1-e^{-C^2/2\theta}})$. And the 95% confidence interval of normalized normal distribution z is [-1.96, 1.96]. Therefore, the interval of $\hat{\theta}$ is $[\theta - \frac{1.96\theta}{\sqrt{1-e^{-C^2/2\theta}}}, \theta + \frac{1.96\theta}{\sqrt{1-e^{-C^2/2\theta}}}]$.

Question 2

(a) My solution

the contribution of a non censored observation to the likelihood is $P(Y < D|\mu, \sigma^2) = \Phi(D; \mu, \sigma^2)$. Therefore, the likelihood of the observed data is,

$$\begin{split} L(\mu, \sigma^2 | \mathbf{x}, \mathbf{r}) &= \prod_{i=1}^n \{ \phi(y_i; \theta)^{r_i} (\Phi(D | \mu, \sigma^2))^{1 - R_i} \} \\ &= \prod_{i=1}^n \{ \phi(x_i; \theta)^{r_i} (\Phi(x_i | \mu, \sigma^2))^{1 - r_i} \} \end{split}$$

Therefore, the log likelihood of the observed data is given by:

$$L(\mu, \sigma^2 | \mathbf{x}, \mathbf{r}) = \sum_{i=1}^n \{r_i \log \phi(x_i; \theta) + (1 - r_i) \Phi(x_i | \mu, \sigma^2)\}$$

(b) My solution

```
load(file = "dataex2.Rdata")
# log likelihood of dataex2
log_like_dataex2 <- function(mean){</pre>
  X <- dataex2[[1]]; R <- dataex2[[2]]</pre>
  sum(R*dnorm(X,mean = mean,sd = 1.5, log = TRUE) + (1-R)*pnorm(X,mean=mean,sd=1.5,log=TRUE))
mle <- maxLik(logLik = log like dataex2, start = c(15))</pre>
summary(mle)
## Maximum Likelihood estimation

```

Therefore, the maximum likelihood estimate of μ is 5.5328.

Question 3

(a) My solution

Since $logit{Pr(R = 0|y_1, y_2, \theta, \psi)} = \psi_0 + \psi_1 y_1$, the missing mechanism is MAR and $\psi = (\psi_0, \psi_1)$ distinct from θ . Therefore, the missing indicator can be ignored for likelihood estimation.

(b) My solution

Since $logit{Pr(R = 0|y_1, y_2, \theta, \psi)} = \psi_0 + \psi_1 y_2$, the missing mechanism is MNAR. Therefore, the missing indicator cannot be ignored for likelihood estimation.

(c) My solution Since logit $\{Pr(R=0|y1,y2,\theta,\psi)\}=0.5(\mu_1+\psi y_1)$, the missing mechanism is MAR. However, (μ_1,ψ) are not distinct from θ . Therefore, the missing indicator cannot be ignored for likelihood estimation.

Question 4

The log likelihood of complete data is:

$$\log L(\beta|\mathbf{y_{obs}},\mathbf{y_{mis}}) = \sum_{i=1}^{m} \left[y_i \log(P_i(\beta)) + (1-y_i) \log(1-P_i(\beta)) \right] + \sum_{i=m+1}^{n} \left[y_i \log(P_i(\beta)) + (1-y_i) \log(1-P_i(\beta)) \right]$$

At iteration t + 1, the E step is given by:

$$\begin{split} Q(\beta|\beta^{(t)}) = & \sum_{i=1}^{m} \left[E_{\mathbf{Y_{mis}}}(y_i|\beta^{(t)}) \log(P_i(\beta)) + (1 - E_{\mathbf{Y_{mis}}}(y_i|\beta^{(t)})) \log(1 - P_i(\beta)) \right] + \\ & \sum_{i=m+1}^{n} \left[y_i \log(P_i(\beta)) + (1 - y_i) \log(1 - P_i(\beta)) \right] \end{split}$$

And we have:

$$E_{\mathbf{Y_{mis}}}(y_i|\beta^{(t)}) = P_i(\beta^{(t)})$$

Therefore,

$$\begin{split} Q(\beta|\beta^{(t)}) &= \sum_{i=1}^{m} \left[P_i(\beta^{(t)}) \log(P_i(\beta)) + (1 - P_i(\beta^{(t)})) \log(1 - P_i(\beta)) \right] + \\ &\qquad \qquad \sum_{i=m+1}^{n} \left[y_i \log(P_i(\beta)) + (1 - y_i) \log(1 - P_i(\beta)) \right] \end{split}$$

```
load(file = "dataex4.Rdata")

# probability of ß
P_beta <- function(x,beta0,beta1){
    exp(beta0+x*beta1) / (1+exp(beta0+x*beta1))
}

# log likelihood
log_like_dataex4 <- function(param){
    beta0<-param[1]; beta1<-param[2]
    x <- dataex4[[1]]; y_modified <- purrr::map2_db1(dataex4$X,</pre>
```

[1] 0.7635572 -4.1509698

Therefore, the maximum likelihood of β is $\hat{\beta}_0 = 0.7635572, \hat{\beta}_1 = -4.1509698.$

Question 5

(a) My solution

Create a vector of observed/latent group data indicator:

$$Z_i = \left\{ \begin{array}{cc} 1, & y_i \sim LogNormal \\ 0, & y_i \sim Exp \end{array} \right.$$

Therefore, the log likelihood of complete data would be:

$$\log L(\theta|y,z) = \sum_{i=1}^{n} z_i \left[\log p - \log(y_i \sqrt{2\pi\sigma^2}) - \frac{1}{2\sigma^2} (\log y_i - \mu)^2 \right] + \sum_{i=1}^{n} (1-z_i) \left[\log(1-p) + \log \lambda - \lambda y_i \right]$$

For the E-step, we need to compute:

$$Q(\theta|\theta^{(t)}) = \sum_{i=1}^{n} E_{Z}[z_{i}|y,\theta^{t}] \left[\log p - \log(y_{i}\sqrt{2\pi\sigma^{2}}) - \frac{1}{2\sigma^{2}}(\log y_{i} - \mu)^{2} \right] + \sum_{i=1}^{n} (1 - E_{Z}[z_{i}|y,\theta^{t}]) \left[\log(1-p) + \log\lambda - \lambda y_{i} \right] + \sum_{i=1}^{n} (1 - E_{Z}[z_{i}|y,\theta^{t}]) \left[\log(1-p) + \log\lambda - \lambda y_{i} \right] + \sum_{i=1}^{n} (1 - E_{Z}[z_{i}|y,\theta^{t}]) \left[\log(1-p) + \log\lambda - \lambda y_{i} \right] + \sum_{i=1}^{n} (1 - E_{Z}[z_{i}|y,\theta^{t}]) \left[\log(1-p) + \log\lambda - \lambda y_{i} \right] + \sum_{i=1}^{n} (1 - E_{Z}[z_{i}|y,\theta^{t}]) \left[\log(1-p) + \log\lambda - \lambda y_{i} \right] + \sum_{i=1}^{n} (1 - E_{Z}[z_{i}|y,\theta^{t}]) \left[\log(1-p) + \log\lambda - \lambda y_{i} \right] + \sum_{i=1}^{n} (1 - E_{Z}[z_{i}|y,\theta^{t}]) \left[\log(1-p) + \log\lambda - \lambda y_{i} \right] + \sum_{i=1}^{n} (1 - E_{Z}[z_{i}|y,\theta^{t}]) \left[\log(1-p) + \log\lambda - \lambda y_{i} \right] + \sum_{i=1}^{n} (1 - E_{Z}[z_{i}|y,\theta^{t}]) \left[\log(1-p) + \log\lambda - \lambda y_{i} \right] + \sum_{i=1}^{n} (1 - E_{Z}[z_{i}|y,\theta^{t}]) \left[\log(1-p) + \log\lambda - \lambda y_{i} \right] + \sum_{i=1}^{n} (1 - E_{Z}[z_{i}|y,\theta^{t}]) \left[\log(1-p) + \log\lambda - \lambda y_{i} \right] + \sum_{i=1}^{n} (1 - E_{Z}[z_{i}|y,\theta^{t}]) \left[\log(1-p) + \log\lambda - \lambda y_{i} \right] + \sum_{i=1}^{n} (1 - E_{Z}[z_{i}|y,\theta^{t}]) \left[\log(1-p) + \log\lambda - \lambda y_{i} \right] + \sum_{i=1}^{n} (1 - E_{Z}[z_{i}|y,\theta^{t}]) \left[\log(1-p) + \log\lambda - \lambda y_{i} \right] + \sum_{i=1}^{n} (1 - E_{Z}[z_{i}|y,\theta^{t}]) \left[\log(1-p) + \log\lambda - \lambda y_{i} \right] + \sum_{i=1}^{n} (1 - E_{Z}[z_{i}|y,\theta^{t}]) \left[\log(1-p) + \log\lambda - \lambda y_{i} \right] + \sum_{i=1}^{n} (1 - E_{Z}[z_{i}|y,\theta^{t}]) \left[\log(1-p) + \log\lambda - \lambda y_{i} \right] + \sum_{i=1}^{n} (1 - E_{Z}[z_{i}|y,\theta^{t}]) \left[\log(1-p) + \log\lambda - \lambda y_{i} \right] + \sum_{i=1}^{n} (1 - E_{Z}[z_{i}|y,\theta^{t}]) \left[\log(1-p) + \log\lambda - \lambda y_{i} \right] + \sum_{i=1}^{n} (1 - E_{Z}[z_{i}|y,\theta^{t}]) \left[\log(1-p) + \log\lambda - \lambda y_{i} \right] + \sum_{i=1}^{n} (1 - E_{Z}[z_{i}|y,\theta^{t}]) \left[\log(1-p) + \log\lambda - \lambda y_{i} \right] + \sum_{i=1}^{n} (1 - E_{Z}[z_{i}|y,\theta^{t}]) \left[\log(1-p) + \log\lambda - \lambda y_{i} \right] + \sum_{i=1}^{n} (1 - E_{Z}[z_{i}|y,\theta^{t}]) \left[\log(1-p) + \log\lambda + \lambda y_{i} \right] + \sum_{i=1}^{n} (1 - E_{Z}[z_{i}|y,\theta^{t}]) \left[\log(1-p) + \log\lambda + \lambda y_{i} \right] + \sum_{i=1}^{n} (1 - E_{Z}[z_{i}|y,\theta^{t}]) \left[\log(1-p) + \log\lambda + \lambda y_{i} \right] + \sum_{i=1}^{n} (1 - E_{Z}[z_{i}|y,\theta^{t}]) \left[\log(1-p) + \log\lambda + \lambda y_{i} \right] + \sum_{i=1}^{n} (1 - E_{Z}[z_{i}|y,\theta^{t}]) \left[\log(1-p) + \log\lambda + \lambda y_{i} \right] + \sum_{i=1}^{n} (1 - E_{Z}[z_{i}|y,\theta^{t}]) \left[\log(1-p) + \lambda y_{i} \right] + \sum_{i$$

$$\text{where } E_Z[z_i|y,\theta^t] = \frac{p^{(t)}\frac{1}{y_i\sqrt{2\pi(\sigma^{(t)})^2}}e^{-\frac{1}{2(\sigma^{(t)})^2}(\log y_i - \mu^{(t)})^2}}{p^{(t)}\frac{1}{y_i\sqrt{2\pi(\sigma^{(t)})^2}}e^{-\frac{1}{2(\sigma^{(t)})^2}(\log y_i - \mu^{(t)})^2} + (1-p^{(t)})\lambda^{(t)}e^{-\lambda^{(t)}y_i}} = \tilde{p}_i^{(t)}.$$

Thus, for the M-step,

$$\frac{\partial}{\partial p}Q(\theta|\theta^{(t)}) = 0 \, \Rightarrow \, p^{(t+1)} = \frac{\sum_{i=1}^n \tilde{p}_i^{(t)}}{n}$$

$$\begin{split} \frac{\partial}{\partial \mu} Q(\theta|\theta^{(t)}) &= 0 \, \Rightarrow \, \mu^{(t+1)} = \frac{\sum_{i=1}^n \tilde{p}_i^{(t)} \log y_i}{\sum_{i=1}^n \tilde{p}_i^{(t)}} \\ \frac{\partial}{\partial \sigma^2} Q(\theta|\theta^{(t)}) &= 0 \, \Rightarrow \, (\sigma^{(t+1)})^2 = \frac{\sum_{i=1}^n \tilde{p}_i^{(t)} (\log y_i - \mu^{(t+1)})^2}{\sum_{i=1}^n \tilde{p}_i^{(t)}} \\ \frac{\partial}{\partial \lambda} Q(\theta|\theta^{(t)}) &= 0 \, \Rightarrow \, \lambda^{(t+1)} = \frac{\sum_{i=1}^n (1 - \tilde{p}_i^{(t)})}{\sum_{i=1}^n (1 - \tilde{p}_i^{(t)}) y_i} \end{split}$$

(b) My solution

```
load(file = "dataex5.Rdata")
em.mixture.lognorm.exp <-</pre>
